(54) Title: ALLEVIATION OF SYMPTOMS ASSOCIATED WITH INFLAMMATORY DISEASE STATES

(57) Abstract

Disclosed are methods for the alleviation of symptoms associated with inflammatory disease states, and more particularly to the inhibition of inflammatory processes associated with the multiple sclerosis disease, by administering a pharmaceutically effective amount of antibody substance immunologically reactive with the common  $\beta$  chain (CD18) of human leukocyte integrins and/or competes with mAb 60.3 for binding to human LFA-1.

## ALLEVIATION OF SYMPTOMS ASSOCIATED WITH INFLAMMATORY DISEASE STATES

This is a continuation-in-part of co-pending U.S. Patent Application Serial No. 08/060,699, filed May 10, 1993 which, in turn, is a continuation of 5 U.S. Patent Application Serial No. 07/915,068, filed July 16, 1992 and now abandoned.

### BACKGROUND OF THE INVENTION

The present invention relates generally to methods for the alleviation 10 of symptoms associated with inflammatory disease states, and more particularly to the inhibition of inflammatory processes involved in the multiple sclerosis disease state through administration of a pharmaceutically effective amount of an antibody substance immunologically reactive with molecules expressed on the surface of leukocytes.

Inflammation is a body process central to a number of diseases and is 15 the body's primary defense against infection. The inflammatory process involves an orchestrated series of events initiated in response to tissue damage. In all cases, this cellular damage ultimately leads to the influx of white blood cells (leukocytes) to the site of injury. As leukocytes arrive at the site of injury, they become metabolically activated and begin to secrete specific proteins (mediators) that are generally of 20 defensive significance, for example, in the eradication of bacteria.

If unregulated, the inflammatory state may persist as a condition known 25 as chronic inflammation. In this setting, the mediators produced may amplify the inflammatory response and cause damage to otherwise normal tissue. Depending upon the body site, such tissue damage may result in chronic diseases such as arthritis, multiple sclerosis, asthma, emphysema, ulcerative colitis, and various autoimmune diseases.

- 2 -

Multiple sclerosis (MS) is a chronic disease characterized by recurrent attacks of neurologic dysfunction due to lesions in the central nervous system. These lesions, termed "plaques," represent areas of axonal demyelination which are the hallmark of multiple sclerosis. The lesions contain inflammatory cells such as lymphocytes, macrophages and neutrophils in areas where myelin is being destroyed.

5                         The classic clinical features of multiple sclerosis include impaired vision and weakness or paralysis of one or more limbs. After a number of years, patients experience a slow, steady deterioration of neurologic function. The disease course is unpredictable and involves exacerbations and remissions in 75% of patients.

10                        Although a few patients die within the first few years of onset, the average duration of disease is greater than 30 years.

There are an estimated 250,000 cases of multiple sclerosis in the United States, with approximately 10,000 new cases occurring each year. The cause is unknown but epidemiology implicates immunologic or infectious factors resulting in a chronic inflammatory brain condition. Multiple sclerosis is a disease of young adults, with 66% of cases occurring at ages 20-40; 60% of the patients are women.

15                       Over one million physician visits occur annually for multiple sclerosis in the United States alone; however, there is currently no effective treatment for multiple sclerosis. Therapy is directed toward the reduction of the severity of acute episodes and prevention of relapses. In acute flare-ups, steroids reduce severity and speed recovery. Experimental therapy with other immunosuppressive agents, such as cyclophosphamide, has been tried, but with limited success.

20

A model for human multiple sclerosis is experimental allergic encephalomyelitis (EAE), an acute inflammatory and demyelinating disease of the central nervous system (CNS). [Rose, *et al.*, *Clin. Immunol. Immunopathol.*, 59:1-15 (1991)]. For both EAE and MS, there is considerable evidence that immunological and inflammatory processes contribute to the pathogenesis of the disease. [Hauser, *et al.*, *Ann Neurol* 13:418-425 (1983); Traugott, *et al.*, *Cell. Immunol.*, 68:261-275 (1982); Rose, *et al.*, *Clin. Immunol. Immunopathol.*, 45:405-423 (1987)]. This is supported by the presence of perivascular mononuclear cellular infiltrates in lesions

25

30

- 3 -

and macrophage-dependent phagocytosis of myelin in the CNS white matter. [Prineas, *et al.*, *Lab. Invest.*, 38:409-421 (1978); Alvord, JC Koetsier, editor; *Handbook of Clinical Neurol.*, 3(47):467-502, Koetsier (ed.); Amsterdam; Elsevier Science Publishers BV (1985)]. The mechanisms by which these blood cells first recognize the brain as a target organ and then traverse the blood brain barrier are not well understood.

The migration of blood cells into extravascular sites of inflammation involves a complex series of events including: i) recognition of an intravascular chemotactic stimulus, ii) adherence to endothelium, iii) diapedesis across the endothelium, and iv) migration through subendothelial connective tissue. [Snyderman, *et al.*, *Science*, 213:830-837 (1981)]. Endothelial cells (EC) found on luminal surfaces of blood vessels are the first cells that leukocytes encounter during migration from the blood to the extravascular space. Molecules expressed by both the leukocytes and by the endothelial cells are important in regulating the adhesive interaction between these two cell types.

One family of leukocyte receptors, variously designated "leukocyte integrins," "leukointegrins," and "CD11/CD18 integrins," are involved in cell-cell and cell-protein interactions of all leukocytes. [Hynes, *Cell*, 48:549-554 (1987); Beatty, *et al.*, *J. Immunol.*, 131:2913-2918 (1983)]. The CD11/CD18 antigen family consists of three heterodimers, each containing a unique  $\alpha$ -chain (CD11a, CD11b, or CD11c), and a common  $\beta$ -chain (CD18). [Sanchez-Madrid, *et al.*, *J. Exp. Med.*, 158:1785-1803 (1983)]. The CD11a/CD18 integrin is referred to as LFA-1; the CD11b/CD18 integrin is referred to as Mac-1; the CD11c/CD18 integrin is referred to as p 150,95.

Numerous murine hybridomas have been generated which produce monoclonal antibodies of varying isotype to the common  $\beta$  chain (CD18) of the leukocyte integrins. These include: mAb 1B4 [IgG2a; Wright, *et al.*, *Proc. Nat'l. Acad. Sci. USA*, 80:5699-5703 (1983)]; mAb 60.3 [IgG2a; Beatty, *et al.*, *J. Immunol.*, 131:2913-2918 (1983)]; mAb TS1/18 [IgG1; Sanchez-Madrid, *supra*]; mAb H52 [Hildreth, *et al.*, *Science* 244:1075-1803 (1989)]; and ATCC T1B 218

- 4 -

[IgG2a Kappa; Springer, *et al.*, *J. Exp. Med.*, 158:586-602 (1983)]. Production of chimeric and humanized monoclonal antibodies against human CD18 is referred to in Law, *et al.*, European Patent Application 440 351 A2, published August 7, 1992.

Monoclonal antibodies directed against the common  $\beta$ -chain of leukocyte integrins completely inhibit adherence of PMNCs to un-activated endothelial cells and certain matrix proteins *in vitro*. [Harlan, *et al.*, *Blood*, 66:167-178 (1985); Zimmerman, *et al.*, *J. Clin. Invest.*, 81:531-537 (1988); Bohnsack, *et al.*, *J. Exp. Med.*, 171:1221-1237 (1990); Luscinskas, *et al.*, *J. Immunol.*, 142:2257-2263 (1989)]. Moreover, the systemic administration of anti-CD11/CD18 antibodies inhibits tissue accumulation of PMNCs. [Springer, *et al.*, *Nature*, 346:425-434 (1990); Jutila, *et al.*, *Transplantation*, 48:727-731 (1989); Arfors, *et al.*, *Blood*, 60:338-340 (1987); Price, *et al.*, *J. Immunol.*, 139:4174-4177 (1987); and, Doerschuk, *et al.*, *J. Immunol.*, 144:2327-2333 (1990)].

Arfors, *et al.*, *supra*, studied the effect of the anti-CD18 antibody, mAb 60.3, on induced PMN accumulation *in vivo* and found that both PMN accumulation and PMN-dependent plasma leakage were abolished in the inflammatory skin lesions of rabbits treated with mAb 60.3 prior to *intra dermal* injection with the chemotactic factors fMLP, leukotriene (LTB<sub>4</sub>) and C5a. These chemotactic agents cause a significant increase in albumin extravasation; extravasation of PMNs at chemotaxin-injective sites is followed by plasma leakage. Curiously, histamine-induced PMN-independent plasma leakage was unaffected by pre-treatment with mAb 60.3.

Hernandez, *et al.*, *Am. J. Physiol.*, 253:H699 (1987) investigated whether PMNs mediate the increase in microvascular permeability produced by ischemia-reperfusion (I/R) by treating cats with either saline, anti-neutrophil serum (ANS), or mAb 60.3. The results indicated that both PMN depletion and prevention of PMN adherence significantly attenuated the increase in microvascular permeability induced by I/R and that prevention of neutrophil adherence with mAb 60.3 afforded protection against I/R-induced microvascular injury. See also, U.S. Patent No. 4,797,277. Similarly, Vedder, *et al.*, *J. Clin. Invest.*, 81:939 (1988) concluded that

- 5 -

increased leukocyte adhesiveness plays an important role in the development of multiple organ injury and death after general ischemia-reperfusion and that this injury may be significantly reduced by blocking leukocyte adherence functions with the mAb 60.3. Their results, however, did not rule out the possibility that other leukocytes or other leukocyte adherence functions may also be involved, as CD18 is present on all leukocytes.

Doerschuk, *et al.*, *supra*, reported on the differential effects of mAb 60.3 on neutrophil (PMN) migration to either pulmonary or peritoneal sites of inflammation in rabbits. Inflammation in the abdominal wall of rabbits was induced following implantation of polyvinyl sponges containing one of the following stimuli: *Streptococcus pneumoniae*, endotoxin (*E. coli*), hydrochloric acid or phorbol myristate acetate (PMA). Peritoneal inflammation was induced by instillation of *S. pneumoniae* and pulmonary inflammation was induced by instilling *intrabronchially* either *S. pneumoniae*, hydrochloric acid, *E. coli* endotoxin, or PMA. Rabbits were pre-treated with either *intra venous* injection of mAb 60.3 or saline 20 minutes prior to initiating inflammation. The results demonstrated that mAb 60.3 inhibited PMN emigration in response to *S. pneumoniae*, hydrochloric acid, *E. coli* endotoxin, or PMA into both the abdominal wall and the peritoneal cavity. However, in the same animals, mAb 60.3 did not alter PMN emigration into the alveolar space, visceral pleura, or bronchial epithelium in response to *S. pneumoniae* or hydrochloric acid. In contrast, mAb 60.3 markedly inhibited PMN emigration into the alveolar space in response to *E. coli* endotoxin and abolished lung emigration in response to PMA. The results demonstrated that there are as yet unidentified organ-specific and stimulus-specific differences in PMN adherence mechanisms that could be due to differences in response of pulmonary and systemic endothelium to identical stimuli or, to the site-specific production of secondary mediators that affect the PMN or endothelial cell.

In addition to U.S. Patent No. 4,797,277, which addresses methods for reperfusion therapy with anti-leukocyte-integrin antibody preparations, a number of quite generalized proposals for therapeutic uses of such antibodies have recently been

- 6 -

made. PCT WO 92/04034, published March 19, 1992, generically proposes the use of anti-CD18 antibodies in the treatment of endotoxin shock. PCT WO 92/03473, published March 5, 1992, proposes use of CD18 peptide fragments and antibodies thereto in the treatment of a "disease". European Patent Application No. 440 451, 5 *supra*, illustrates usefulness of recombinant humanized anti-CD18 antibodies in the treatment of rabbit dermal inflammation but projects utility in treatment of inflammation in "lung, central nervous system, kidney, joints, endocardium, pericardium, eyes, ears, skin, gastrointestinal tract and urogenital systems." Although multiple sclerosis is proposed as one of many disease states which "may be 10 responsive to recombinant human anti-CD18 antibody," no studies of the effect of such antibodies on any chronic inflammatory disease states are reported in the published European Patent Application.

With particular reference to MS, Raine *et al.*, *Lab. Investigations*, 15 63)4:476-489 (1990) noted that a variety of adhesion molecules appear to be involved in the lymphocyte homing and cell triggering processes extant in the disease state. Raine *et al.* further noted that disruption of any of the involved ligand pairs [e.g., LFA-1/ICAM-1, CD-2/LFA-3, CD4/class II MHC (HLA-DR)] might lead to alterations in lymphocyte traffic, effector cell activation, or effector cell function. The same research group later reported, however, that while treatment of EAE mice 20 with anti-ICAM-1 antibodies resulted in some reduction in the degree of inflammation, treatment with anti-LFA-1 antibodies was lethal at high doses and had no effect on CNS changes at lower doses. See, Cannella *et al.*, *J. Neuropathol. Exp. Neurol.*, 51:382 (May, 1992). See also, Racke *et al.*, *Journal of Cellular Biochemistry*, 17A:355 (1993) reporting that low doses of anti-ICAM-1 and anti-LFA- 25 1 antibodies resulted in more severe disease in EAE mice, while higher doses appeared to delay disease onset and only treatment with both antibody preparations allowed observation of suppression of clinical signs; and Welsh *et al.*, *J. Neuroimmunology*, 43:161-168 (1993) reporting that anti-LFA-1 antibody treatment augmented the severity of disease symptoms in adoptively transferred EAE.

- 7 -

There thus continues to exist a need in the art for therapeutic materials and regimens for the treatment of inflammation associated with multiple sclerosis.

#### BRIEF SUMMARY OF THE INVENTION

The present invention provides novel and effective methods for the treatment of inflammatory processes and the alleviation of symptoms associated with the multiple sclerosis disease state comprising administering a therapeutically effective amount of an anti-CD18 and/or anti-LFA-1 antibody substance. Alternatively stated, the present invention addresses the use of anti-CD18 and/or anti-LFA-1 antibodies for the manufacture of a medicament for alleviation of symptoms associated with the multiple sclerosis disease state.

Antibody substances useful in practice of the present invention include monoclonal and polyclonal antibodies, antibody fragments, single chain antibodies, chimeric and/or CDR-grafted (including humanized) antibodies and the like which are specifically immunoreactive with one or more epitopes presented by the common  $\beta$ -chain (CD18) of human leukocyte integrins. Antibodies may be of any class or subclass including IgG, IgA, IgD, IgE and/or IgM. Among the preferred antibodies for practice of the invention is mouse monoclonal antibody mAb 60.3 of the IgG2a isotype.

Also provided by the present invention are monoclonal anti-human CD18 antibodies produced by hybridoma cell lines designated 23F2G (A.T.C.C. HB 11081) 23I11B and 22F12C. These and antibodies produced by hybridomas 22B3B and 22J4A are characterized as competitive inhibitors of the binding of mAb 60.3 to human LFA-1 on Hut78 cells. The 23F2G antibody produced by A.T.C.C. HB 11081 has correspondingly been "humanized" and transformed mammalian cells expressing humanized forms of the mouse 23F2G antibody have been deposited under accession Nos. A.T.C.C. CRL 11397 and CRL 11398.

Other aspects and advantages of the present invention will be apparent upon consideration of the enclosed detailed description of embodiments thereof, reference being had to the drawing wherein:

- 8 -

Figures 1A, 1B, 1C and 1D and Figures 2A, 2B, 2C, 2D, 2E, 2F and 2G present magnetic resonance images illustrating results of practice of the invention in the Experimental Allergic Encephalomyelitis (EAE) model system;

5 Figures 3A and 3B and Figures 4A, 4B, 4C and 4D represent histological results of practice of the invention in the EAE model system; and

Figure 5 and 6 are schematic representations of expression vectors encoding humanized heavy and light chains, respectively, of an antibody of the invention.

#### DETAILED DESCRIPTION

10 The following detailed description illustrates practice of the invention through use of the mouse monoclonal anti-CD18 antibody mAb 60.3, mouse monoclonal antibody 23F2G and humanized antibody 23F2G to alleviate progression of Experimental Allergic Encephalomyelitis (EAE) in macaque monkeys. Non-human primates induced to develop EAE, an acute inflammatory disease of the central nervous system and a model of the human disease MS, were chosen because of the many immunological and neurophysiological similarities EAE shares with MS (Rose, et al., *supra.*) and because the CD18 antigen recognized by mAb 60.3 is present in high density on monkey peripheral blood leukocytes (Rose, et al., *Clin. Immunol. Immunopathol.*, 44:93-106 (1987)).

20 Example 1 relates to the induction of EAE in monkeys. Example 2 describes treatment by mAb 60.3 antibody infusion and Example 3 relates to the evaluation of disease progression as monitored by a combination of clinical evaluation, blood analysis, and magnetic resonance imaging, including immunocytochemical staining of frozen tissue sections obtained post-mortem. Example 4 describes the preparation of hybridoma cell lines producing anti-human CD18 antibodies and Example 5 relates use of monoclonal antibodies from hybridoma 23F2G in treatment of EAE. Example 6 addresses humanization of antibody 23F2G and Example 7 describes additional treatments of EAE macaque monkeys with antibody 23F2G and humanized 23F2G.

#### SUBSTITUTE SHEET

- 9 -

### EXAMPLE 1

#### Induction of EAE

18      Eighteen male monkeys *Macaca fascicularis* weighing 2-3 kg were sensitized to myelin basic protein (BP) by the *intra dermal* injection of 0.1 ml of an emulsion containing 5.0 mg of monkey BP and 0.5 mg of heat-killed *M. tuberculosis*.  
5      Each animal was obtained and housed by the Regional Primate Research Center at the University of Washington, Seattle. The Primate Center conforms to the National Institutes of Health Guide for the Care and Use of Laboratory Animals. Ten days after sensitization to BP, each animal was outfitted with a femoral catheter and tether  
10     to facilitate blood sampling and the administration of treatments or anesthetics for magnetic resonance imaging (MRI). The animals were maintained on intravenous heparin (18 units/hour) to prevent blood clots from forming in the intra venous lines.

15     The animals were randomly admitted to specific treatment groups before they were sensitized to BP. This was done to schedule MRI and to prevent the severity of clinical signs at the onset from influencing the choice of therapy. Primate Center personnel, responsible for deciding when animals should be treated or sacrificed, were blinded regarding the treatment history of each animal. Table 1 below provides a statement of criteria for determination of clinical signs and grades of EAE in the animals.

- 10 -

**TABLE 1**  
**CLINICAL SIGNS AND GRADES OF EAE IN MACAQUES**

	Score	Signs
5	?	Prodromal signs, including weight loss, anorexia, yawning, slow response to stimuli, irritability
	±	Mild neurologic signs, including "headache" (acute distress), "apathy" (indifference), hypokinesia, drooling, clumsiness in using limbs, nystagmus
10	+	Moderate neurologic signs, including akinesia, blindness, ataxia, tremor, ptosis, seizures, paresis, incontinence
	++	Severe neurologic signs including somnolence, paraplegia, hemiplegia, or quadriplegia
	+++	Moribund state with semicomma, coma, decerebration or decortication
15	D	Death

#### EXAMPLE 2

##### Treatment By Antibody Infusion

At the onset of definite clinical signs (± to +) six EAE animals received a bolus injection of mAb 60.3 (2 mg/kg) and dexamethasone (4 mg/kg). Dexamethasone was administered to reduce the incidence of severe acute EAE which is rapidly fatal within 48 hours unless treated immediately. Severe acute EAE occurs in approximately 25% of animals induced to develop EAE and is caused by edema in areas involving or impinging upon the brain stem or cerebral cortex. Following injection of the bolus, these six animals were treated by continuous infusion of mAb 60.3 (2 mg/kg/day) for seven days. Over the seven day treatment period, the dose of dexamethasone, which started at 4 mg/kg, was halved every two days until only 1 mg had been in effect for three days. Six control EAE animals were treated only with dexamethasone, following the same protocol outlined above, and six additional controls were treated with continuous infusion of saline.

- 11 -

Animals that improved and/or stabilized as a result of therapy were sacrificed six weeks after the onset of clinical signs. Animals that experienced a clinical relapse (clinical signs  $\geq ++$ ) some time after the cessation of treatment and before six weeks had elapsed, were sacrificed shortly after the onset of the relapse.

5 Animals that did not respond well to therapy and continued to deteriorate clinically (clinical signs  $\geq ++$ ) were sacrificed without completing the treatment program. The statistical significance of differences in survival times in each treatment group was determined by two-tailed Student *t* analysis.

### EXAMPLE 3

#### 10 Evaluation of Disease Progression

Disease progression was monitored by a combination of clinical evaluation, blood analysis and magnetic resonance imaging. Clinical evaluations were performed twice daily.

15 As indicated in Table 2 below, all of the animals in this study developed clinical signs of EAE 13-26 days after sensitization to myelin basic protein.

In Table 2, listing of animal numbers in boldface identified animals scanned by MRI; the Onset/Grade column reflects the day of onset after sensitization and the severity of clinical signs (see Table 1) at onset; the Survival/Grade column reflects days of survival post-onset and severity of clinical signs at time of sacrifice.

- 12 -

TABLE 2

	86209	15 days/+	saline	1 day/++

- 13 -

As indicated in Table 2, all eighteen animals developed clinical signs of EAE which ranged in severity from  $\pm$  to + at the onset of disease. Six of the eighteen EAE animals (33%) died of severe acute EAE 1-5 days after onset. Four of the six had been treated with saline, one with dexamethasone, and one with a combination of dexamethasone and mAb 60.3. The remaining twelve animals were sacrificed at various times after onset either because they had deteriorated clinically or because they had completed the six-week post-treatment protocol.

Out of six mAb-treated animals, five either improved or stabilized with continuing, but not worsening, clinical signs. Animal 89071 improved, but suffered an acute relapse two weeks after the cessation of treatment and was sacrificed at 21 days. Animal 89074 was sacrificed at 13 days, one week after the cessation of treatment, to investigate an abnormal lipid signal detected by magnetic resonance spectroscopy (MRS), a technique being developed for studies of demyelination in the nonhuman primate [Richards *et al.*, *New York, Soc. Mag. Reson. Med.* 2: p.1043 (1990)]. This animal had improved as a result of therapy and was clinically stable at the time of sacrifice. Animals 89075, 89080, and 89069 were all clinically stable six weeks after onset. The mean survival time of mAb 60.3-treated animals was 30 days. Control animals treated with saline (excluding animal 87220) survived 1-5 days after onset, with a mean survival time of 3 days. Animals treated with dexamethasone survived 1-17 days after onset, with a mean survival time of 7 days, 3 of 6 dying of their disease 1-2 days after onset, and 3 of 6 surviving 9,13 and 17 days, respectively, until they were sacrificed due to deteriorating clinical signs ( $\geq ++$ ).

#### Magnetic Resonance Imaging

MRI was used to map the anatomic distribution of the lesions in all six of the mAb-treated EAE animals, two dexamethasone-treated animals, and two saline-treated animals. Conventional spin-warp imaging was performed using a General Electric CSI-II NMR imager/spectrometer (2 Tesla magnet) as described in Rose *et al.*, *Biomed. and Pharmacother.*, 43:347-353 (1989). Images were acquired

- 14 -

once a week before the onset of clinical signs and twice a week after the onset of clinical signs. The animals were anesthetized with ketamine and positioned in the magnet so that the center of the brain was at magnet iso-center. Coronal T2-weighted images (TE=80 msec, TR=3000 msec) were used to find abnormal and normal brain regions. Lesions were detected in 60% of the scanned animals on or before the onset of clinical signs. Most lesions were localized in the cerebral white matter, optic tracts, visual radiations or brainstem. The lesions were identified as areas of increased brightness (white) in a T2-weighted MR image. Of the four control animals that were scanned, only one survived long enough to obtain post-treatment scans. In this dexamethasone-treated animal (87069) a brainstem lesion, detected one day before the onset of clinical signs, progressed in size and intensity until the animal was sacrificed nine days later as shown in Figure 1. Plate A represents a "normal" brain scan, 21 days after sensitization; Plate B reveals detection of a brainstem lesion two days after onset of clinical signs i.e., 28 days post sensitization; Plates C and D illustrate gradual progression of the brainstem lesion 35 and 38 days after sensitization, respectively.

Following treatment with mAb 60.3, the MRI lesions detected in 5 of 6 animals diminished in both size and intensity. Three animals (89075, 89071, and 89074) had evidence of brainstem lesions at the onset of clinical signs. Although such lesions are frequently fatal if untreated [Shaw *et al.*, *Ann. Neurol.* 24:738-748 (1988)], these lesions disappeared in all three animals following treatment with mAb 60.3. Figure 2 demonstrates the progression of the brainstem lesion in animal 89071. In the Figure, Plate A illustrates a normal brain scan 15 days post sensitization; Plate B shows a brainstem lesion at the onset of clinical signs, i.e., 18 days after sensitization; Plates C through F illustrate gradual resolution of the brainstem lesion through antibody treatment as monitored at 22, 25, 29 and 32 days post sensitization; Plate G illustrates reappearance of a lesion in the same region which was accompanied by clinical relapse 39 days post sensitization and 14 days after cessation of treatment. Enlarging lesions are identified as prominent areas of increased intensity (white) on the scans. As noted above, two weeks after the treatment was

- 15 -

discontinued, 89071 clinically relapsed and MR images demonstrated a larger, more intense lesion in the brainstem. The relapse was not treated and the animal was sacrificed.

5 Animal 89080 developed a major hemorrhagic lesion in the lateral geniculate nucleus and striatum. Hemorrhagic lesions are usually fatal and usually do not respond to treatment (Shaw *et al.*, *supra*) but this lesion almost completely disappeared following administration of mAb 60.3. Animal 89069 had the mildest disease of any of the animals, as determined by MRI, with several small, but intense, sub-cortical white matter lesions that disappeared following treatment.

10 Two of the longest surviving animals (89080 and 89069) developed a chronic disease characterized by the appearance of new, smaller, MRI-detectable lesions 25 and 22 days, respectively, after the cessation of treatment. These secondary lesions were not as severe as the first lesions and were accompanied by milder clinical signs which were not treated. Animal 89074 was sacrificed 13 days  
15 after the onset of disease, to investigate an abnormal lipid signal detected by MRS. At the time of sacrifice, six days after stopping treatment, his initial lesions were gone, but a new smaller subclinical lesion had appeared on the opposite side of the brain. No new lesions were ever detected in animal 89075 after cessation of treatment.

20 Cryostat sections of cerebellum or cerebrum were stained with hematoxylin and eosin and by the immunoperoxidase technique in conjunction with mAbs to human leukocyte membrane antigens in order to analyze the composition of the cellular infiltrates. Immunocytochemical staining with mAb 60.3, which recognizes a CD18 determinant common to all leukocytes, was used to confirm the presence of leukocytes in EAE lesions. A tissue section obtained from the brain of animal 89070 and stained with mAb 60.3 is shown in Figure 3. In Panel A, at 390X magnification and stained with rabbit anti-mouse IgG, murine IgG coated cells are revealed in the lumen of blood vessels but not in brain tissue; and, in Panel B, at 390X magnification and stained with mAb 60.3, massive infiltration of PMBCs is seen in the exudate and extending out into adjacent white matter.  
25  
30

- 16 -

Animal 89070 was the only mAb-treated animal to die before completion of treatment. Brain tissue taken from this animal was stained with a goat anti-mouse Ig antibody in order to determine whether the treatment mAb had entered the CNS before the animal died. MAb 60.3 reacts with both leukocytes and brain microglia. If this mAb had crossed the blood-brain-barrier during the treatment period, it was expected that a staining pattern similar to that shown in Figure 3, Panel B might be obtained. Alternatively, if the treatment mAb entered the CNS, bound only to blood leukocytes, the microglia would not have been stained. Instead, murine Ig-coated cells were only detectable in the vessel lumen, and not at all in the perivascular spaces. The absence of any positively stained leukocytes in the lesion stained with goat anti-mouse Ig, suggests that the animal died of an inflammatory condition existing before treatment was initiated and that the treatment antibody was given too late to be effective.

#### Effect of Treatments on Leukocyte Counts

The hematologic hallmarks of untreated EAE are a progressive leukocytosis and lymphopenia prior to the onset of clinical signs. The leukocytosis can represent as much as a four-fold increase in the number of circulating PMNC and no significant changes in the frequency or absolute numbers of monocytes, eosinophils, or basophils. Following successful treatments of EAE, the absolute numbers of lymphocytes and PMNC return, fairly soon after the initiation of treatment, to pre-sensitization levels. Thus, continuous monitoring of blood leukocytes provides a useful measure of disease progression which complements the clinical evaluation and magnetic resonance imaging.

Blood was drawn on a weekly basis until the onset of clinical disease and then more frequently. One-half ml was sent to the hematology laboratory for WBC and differential counts. The results are set out in Table 3 below providing white blood cell number ( $\times 10^3$ ) per  $\text{mm}^3$  whole blood. "NA" indicates that data was not available. A dashed line indicates that the animal was sacrificed at this time.

	Day 2	20.2	8.4	22.5	29.0	--	--
	Day 4	30.1	8.0	--	--		
	Day 7	--	--				

In animals treated with mAb 60.3 and dexamethasone, a delayed resolution of the leukocytosis was observed as compared to animals treated with dexamethasone alone as revealed in Table 3. In two of the dexamethasone-treated animals that survived 9 days or longer, the white blood cell counts dropped to presensitization levels two days after the initiation of treatment. In mAb 60.3-treated animals, a pronounced leukocytosis (4-12 fold above presensitization values) was observed which lasted for the entire treatment period. In these animals, the WBC returned to presensitization levels 3-7 days only after the treatment period had ended. Transient episodes of lymphopenia and leukocytosis continued to be observed in the surviving animals, and could be correlated in some cases with episodes of clinical relapse.

- 19 -

Reaction of the treatment mAb with blood leukocytes was confirmed by staining cells with anti-murine Kappa chain mAb (Becton-Dickinson, San Jose, CA). Flow cytometric analysis was performed with a FACSCAN Analyzer (Becton Dickinson, San Jose, CA). Forward and right-angle scatter gates were set on lymphocytes or large polymorphonuclear granulocytes for analysis of staining patterns. The results for lymphocytes are set out in Table 4 below.

TABLE 4

% MURINE Ig-COATED CELLS

	ANIMALS:	89070	89075	89080	89069	89071	89074
10	Day						
	Presens	0	0	0	0	0	0
	Onset	0	0	0	0	0	0
	Day 2	---	96.6	97.7	94.2	96.7	98.2
	Day 4		93.8	95.2	91.2	97.0	49.8
15	Day 7		95.2	99.1	94.9	95.4	27.2
	Day 10		0	2.6	11.2	19.6	1.4

The dose of mAb given to the animals was in all instances sufficient to coat >95% of circulating white blood cells and, as indicated in Table 5, to maintain detectable levels of free antibody in circulation. Data in the Table represent micrograms of circulating murine IgG per mm<sup>3</sup> whole blood.

- 20 -

TABLE 5

CIRCULATING MURINE IgG

Day

	ANIMALS:	89070	89075	89080	89069	89071	89074
5	Presens	0	0	0	0	0	0
	Onset	0	0	0	0	0	0
	Day 2	--	65	70	15	28	34
	Day 4		80	70	65	25	15
	Day 7		90	58	4	7	28
10	Day 10		0	0	0	0	0

After 7 days, the injected mAb was no longer detectable in the circulation. The disappearance of the murine Ig coincided with the appearance of monkey anti-murine Ig antibodies in the circulation of each animal.

Neuropathology

15 To confirm the diagnosis of EAE, the brains and spinal cords of each BP-sensitized animal were examined postmortem. The animals were euthanized by Nembutal overdose and brains and spinal cords were removed and dissected so that fresh-frozen samples could be obtained before the larger blocks were fixed in 10% neutral formalin. Representative blocks of tissue were embedded in paraffin and sections were stained with hematoxylin and eosin, gallocyanin-Darrow red, luxol fast blue (LFB) combined with periodic acid Schiff (PAS) and hematoxylin and with Holmes' axon stain alone or combined with LFB to differentiate demyelination from necrosis. Frozen sections of mirror-image blocks were stained with Oil Red O (ORO) [Kil, *Stain Technology*, 47:271, (1972)] to identify lipid-filled macrophages.

20

25 All eighteen EAE animals were evaluated histologically postmortem for evidence of EAE. All had microscopic evidence of either mild to severe acute EAE or hyperacute EAE that generally correlated with the severity and duration of the disease. All but 2 of the 12 control animals showed either predominantly hyperacute

- 21 -

lesions characterized by hemorrhages, subtotal necrosis, demyelination, and diffuse massive infiltrations of neutrophils into the CNS parenchyma; or severe acute perivascular lesions which were more compact, more confined to the perivascular spaces than the hyperacute lesions and composed predominantly of lymphocytes and macrophages, but some neutrophils, and with abundant demyelination as well as some axonal debris. The two exceptional control monkeys, with EAE of 13-17 days duration, had a mixture of lesions ranging from mild to severe demyelinating lesions, composed predominantly of lymphocytes and macrophages with abundant myelin debris and little or no axonal reaction. All but one of the mAb-treated monkeys had a combination of: (a) older well developed demyelinated plaques with abundant myelin debris, sudanophilic lipid and little or no axonal reaction or lymphocytic infiltrate; and (b) more recent lesions corresponding to the terminal untreated relapses, which were compact, confined to perivascular spaces, with varying proportions of lymphocytes, monocytes, or neutrophils (consistent with diagnoses of mild to severe acute EAE ) and some myelin debris. These two types of lesions, found in the same animal (#89069), are shown in Figure 4.

In Figure 4, Panel A, at two-fold magnification, numerous inflammatory (area 1) and/or demyelinating (area 2) lesions can be ascertained in the white matter; in Panel B, at 325X magnification, area 2 of Panel A is revealed as being composed predominantly of macrophages scattered diffusely through the tissue and about blood vessels, with the small black granules constituting PAS positive glyco-lipoproteins; and in Panels C and D, at 130X and 325X magnification, respectively, area 1 of Panel A is revealed as being composed predominantly of PMNCs and no PAS positive insoluble glycoproteins.

## 25 Summary Of Results

Monitoring disease progression by a combination of clinical evaluation, blood cell fluctuations, and magnetic resonance imaging (MRI) revealed the following. Antibody treated animals survived significantly longer than either dexamethasone- or saline-treated animals ( $p < 0.02$ ;  $p < 0.001$ ; respectively). The

- 22 -

effectiveness of this therapy is further confirmed by visualization by magnetic resonance imaging (MRI). The almost complete disappearance of major lesions in the brainstems of three different animals was unprecedented as brainstem lesions are rapidly fatal in untreated animals. The disappearance of MRI-detectable lesions following administration of mAb 60.3 demonstrates a potent effect on the inflammatory reactions producing edema in the brain lesions. MAb 60.3 is known to inhibit plasma leakage *in vivo* [Arfors *et al.*, *Blood*, 60: 338-340, (1987)], probably the most important factor in improvement in MRI-detectable lesions, as changes in the tissue water characteristics can be visualized by changes in image intensity on the MRI scans.

The severity of clinical signs at the onset of EAE was not uniform because individual monkeys responded differently to sensitization with myelin BP. Nevertheless, there was no correlation between the severity of clinical signs at the onset of EAE and the ability of animals to respond to treatment. Of the six mAB-treated animals, four were + at the onset of clinical signs and 2 were  $\pm$ . Of the twelve control animals (six dexamethasone-treated and six saline-treated), 8 were + and 4 were  $\pm$ , essentially the same distribution as the mAb-treated group. No correlation was found between the severity of clinical signs at the onset and the potentially stressful procedure of MRI examination under general anesthesia. Of the ten animals scanned by MRI, six were + at the onset of clinical disease and four were  $\pm$ . One might have expected the additional handling involved in scanning the animals, as well as the frequent administration of anesthetics, to result in a generalized suppression of the immune response. [Wall *et al.*, *Lab Animals*, 19:138-144 (1985), Thomas *et al.*, *Clin. Exp. Immunol.*, 47:457-466 (1982)]. However, the results do not support this hypothesis.

The dexamethasone-treated animals did have longer mean survival time (7 days) than the saline-treated controls (3 days), but the difference was not statistically significant ( $p < 0.1$ ). Thus, although dexamethasone slowed down the disease process, it had little apparent effect on the final outcome of the disease. Co-

- 23 -

administration of mAb 60.3, on the other hand, significantly prolonged survival and in some cases completely reversed the clinical and MRI appearances of EAE.

#### EXAMPLE 4

5 Six to twelve week old Balb/c mice (Charles River Biotechnical Services, Inc., Wilmington, Massachusetts, IACUC #901103) were immunized with human T cell line Hut 78 to generate anti-CD18 antibodies. For each of two hybridoma-generating fusions (designated fusions 22 and 23) two Balb/c mice were bled retro-orbitally for the collection of pre-immune serum on day 0. On day 2, each animal received a total of  $5 \times 10^6$  Hut 78 cells in 0.2 ml sterile PBS intravenously.

10 10 The mice were then immunized at two week intervals for six weeks and then at monthly intervals for three months. The final monthly boost was of glutaraldehyde fixed Hut 78 cells. Cells were fixed by mixing equal volumes of cells ( $2 \times 10^7$ ) and glutaraldehyde (0.1% so that the final concentration of the fixative was equal to 0.05%). The mixture was incubated with swirling for thirty seconds and an equal

15 15 volume of 0.2M glycine (in PBS) was added to block the reaction. The reaction mixture was washed once with 0.2M glycine (in PBS) and twice with PBS. Cells were resuspended in PBS at a concentration of  $5 \times 10^6$  cells per 0.2 ml PBS. Immune serum was collected via retro-orbital bleeding on day 56 and tested by FACS to determine its reactivity with the immunogen (Hut 78 cells). Three days prior to

20 20 the projected fusion date, the animals were immunized by intravenous injection with a final dose of  $5 \times 10^6$  glutaraldehyde fixed cells.

25 For each fusion, the spleen from the mouse displaying the highest immune serum titer against the immunogen was removed steriley. A single-cell suspension was formed by grinding the spleen between the frosted ends of two glass microscope slides submerged in serum free RPMI 1640, supplemented with 2 mM L-glutamine, 1 mM sodium pyruvate, 100 units/ml penicillin, and 100  $\mu$ g/ml streptomycin (RPMI)(Gibco, Canada). The cell suspension was filtered through sterile 70-mesh Nitex cell strainer (Becton Dickinson, Parsippany, New Jersey), and washed twice by centrifuging at 200 g for 5 minutes and resuspending the pellet in

- 24 -

20 ml serum free RPMI. Thymocytes taken from 3 naive Balb/c mice were prepared in a similar manner.

NS-1 myeloma cells, kept in log phase in RPMI with 11% fetal bovine serum (FBS)(Hyclone Laboratories, Inc., Logan, Utah) for three days prior to fusion, 5 were centrifuged at 200 g for 5 minutes, and the pellet was washed twice as described in the foregoing paragraph. After washing, each cell suspension brought to a final volume of 10 ml in serum free RPMI, and 10  $\mu$ l was diluted 1:100. 20  $\mu$ l of each dilution was removed, mixed with 20  $\mu$ l 0.4% trypan blue stain in 0.85% saline (Gibco), loaded onto a hemacytometer (Baxter Healthcare Corp., Deerfield, Illinois) 10 and counted.

For each fusion,  $2 \times 10^8$  spleen cells were combined with  $4 \times 10^7$  NS-1 cells, centrifuged and the supernatant was aspirated. the cell pellet was dislodged by tapping the tube and 2 ml of 37°C PEG 1500 (50% in 75 mM Hepes, pH 8.0)(Boehringer Mannheim) was added with stirring over the course of 1 minute, 15 followed by adding 14 ml of serum free RPMI over 7 minutes. An additional 16 ml RPMI was added and the cells were centrifuged at 200 g for 10 minutes. After discarding the supernatant, the pellet was resuspended in 200 ml RPMI containing 15% FBS, 100  $\mu$ M sodium hypoxanthine, 0.4  $\mu$ M aminopterin, 16  $\mu$ M thymidine (HAT) (Gibco), 25 units/ml IL-6 (Boehringer Mannheim) and  $1.5 \times 10^6$  20 thymocytes/ml. The suspension was dispensed into ten 96-well flat bottom tissue culture plates (Corning, United Kingdom) at 200  $\mu$ l/well. Cells in plates were fed on days 2, 4 and 6 days post fusion by aspirating approximately 100  $\mu$ l/well plating medium described above except containing 10 units/ml IL-6 and lacking thymocytes.

On day 10 culture supernatants were taken from each well, pooled by 25 column or row and analyzed for the presence of an antibody capable of competing with an FITC-60.3 conjugate (prepared according to Goding, in "Monoclonal Antibodies: Principles and Practice," 2d Ed., p. 241-280, Academic Press, New York, 1986) for binding to Hut78 cells. The competition assay was performed as follows. Twenty-five  $\mu$ l of a cell suspension containing  $10 \times 10^6$  Hut78 cells/ml was 30 combined with 25  $\mu$ l of a sub-saturating dose of FITC-60.3 ( $\times 2560 \equiv 0.8 \mu$ g/ml)

- 25 -

and 50 ml  $\mu$ l of fusion supernatant and incubated for 30 min at 4°C, washed by adding culture media to the cell mixture and centrifuging at 1800 rpm for three minutes. The supernatant was removed by aspiration and the pellet was washed twice with flow cytometric analysis (FACS) medium containing RPMI, 2% PBS and 0.1% Na<sub>3</sub>. The reaction mixture was fixed by addition of 1% paraformaldehyde (pH 7.2 in PBS) and transferred to polystyrene tubes for FACS using a Becton Dickenson FACscan analyzer. Of the 960 hybridomas generated in fusion 22, the supernatant of hybridoma No. 22F12C inhibited binding of FITC-60.3 by about 90%; supernatants from hybridoma Nos. 22J4A and 22B3B inhibited binding by about 40% and 10% respectively. Two hybridomas from fusion 23, 23F2G and 23I11B, produced antibodies which inhibited FITC-60.3 binding by  $\geq$  95%. These five hybridomas were cloned. Hybridoma cell line 23F2G was deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, M.D. 20852 U.S.A. on June 30, 1992 and accorded accession number A.T.C.C. HB 11081. The isotype of the antibody produced by hybridoma cell line 23F2G (referred to herein as mAb 23F2G) was determined to be IgG2a. Hybridomas 22F12C and 23I11B also produced antibodies of the IgG2a isotype, while hybridomas 22B3B and 22J4A produced IgG1 antibodies.

Antibodies from hybridomas 22F12C, 23F2G and 23I11B were all found, in varying degrees, to: (1) block adhesion of human T cells to activated HUVEC monolayers; (2) block aggregation of 13-acetate (PMA) activated Con A blast cells phorbol 12-myristate; and (3) induce demargination of white blood cells in rabbits. The ability of the IgG1 antibodies produced by hybridomas 22B3B and 22J4A to block adhesion is as yet undetermined; mAb 22J4A was able to block aggregation, but mAb 22B3B was not; both antibodies induced demargination, but to a lesser degree than the others or mAb 60.3. Based on the screening results noted above, it appears likely that, notwithstanding the ability to compete for binding of mAb 60.3 to LFA-1 on Hut 78 cells, mAb 22B3B and 22J4A are specific for an epitope present on the CD11a component of LFA-1 or an epitope associated with the CD11a/CD18 heterodimer rather than with an epitope of CD18.

- 26 -

A comparison was made between the amino acid sequence of the variable region of mAb 60.3 presented by L. Harris at San Francisco, California on May 26-27, 1992 in a poster presented at a conference entitled "Cell Adhesion Molecules In Inflammation" organized by International Business Communications (South Natick, Mass.) and the amino acid sequence of the variable region of mAb 23F2G. Gross differences were found, despite the fact that 23F2G competed with 60.3 for binding to Hut78 cells. While these differences are suggestive of the possibility that the antibodies bind adjacent, different epitopes on CD18, confirmation of this possibility will have to await definitive epitope mapping studies.

10

#### EXAMPLE 5

Hybridoma 23F2G was amplified by the ascites method and antibody was purified by affinity chromatography on Protein A under pyrogen-free conditions. From 25 ml of ascites, 120 mg of antibody preparation was isolated. This preparation contained only about 4 endotoxin units per mg.

15

Two *Macaca fascicularis* monkeys were then involved in a study to preliminarily determine the ability of mAb 23F2G to alleviate EAE symptoms. The EAE induction procedures were essentially as in Example 1. Two animals, Nos. 89161 and 89186, sensitized to 1.0 mg of purified monkey basic protein and developed hyperacute hemorrhagic EAE 18 and 20 days post sensitization, respectively. Animal 89161 died within 12 hours of onset and before treatment with dexamethasone could be initiated. Animal 89186 was treated for a week with both dexamethasone (3 days at 4 mg/kg, 2 days at 2 mg/kg and 2 days at 1 mg/kg) and mAb 23F2G (7 days at 2 mg/kg, i.v.). The animal improved dramatically with complete resolution of paralysis three days after initiation of treatment. Lesions detected by MRI resolved four days after cessation of treatment and the animal improved dramatically with complete resolution of paralysis. Eight days following cessation of treatment, the animal relapsed and was sacrificed. Hematologic analysis revealed that mAb 23F2G caused steady demargination of leukocytes which peaked on the last day of treatment. The white blood cell count rose from  $22.7 \times 10^3$  on the

20

25

- 27 -

day of clinical onset to  $82 \times 10^3/\text{mm}^3$  on the last day of treatment. The antibody showed saturation of blood lymphocytes at the dose administered.

#### EXAMPLE 6

##### Humanization of 23F2G Antibody Variable Regions

###### 5 A. Determination of Variable Region Sequences

Total RNA was isolated from the hybridoma cell line 23F2G (A.T.C.C. HB 11081) and first strand cDNA was synthesized using the total RNA as a template. The first strand cDNA was in turn used as a template for PCR reactions to obtain double-stranded DNA fragments encoding the variable regions of both the heavy and light chains of mAb 23F2G.

10 The forward primer used to clone the heavy chain variable region was primer HFR1-4, the sequence of which is set out below in IUPAC nomenclature as SEQ ID NO: 1.

15 Forward Primer HFR1-4 (SEQ ID NO: 1)

CGATACGAATTCAGGTSMARCTGCAGSAGTCWG

The 3' nucleotides of the primer correspond to the region encoding the first seven amino acids of mature mouse immunoglobulin heavy chains, while the underlined nucleotides of the primer encode an *Eco*RI site to facilitate cloning of the PCR fragment generated. The reverse primer used to clone the heavy variable region sequences was primer HG2A-1, the sequence of which is set out below in IUPAC nomenclature as SEQ ID NO: 2.

20 Reverse Primer HG2A-1 (SEQ ID NO: 2)

GCTATCGGATCCGGARCCAGTTGTAYCTCCACACAC

25 The 3' end of primer HG2A-1 encodes the complement of codons 127-136 in the mouse IgG<sub>2A</sub> constant region [according to the numbering system of Kabat *et al.*, "Sequences of Proteins of Immunological Interest", U.S. Department of Health and Human Services, NIH Publication No. 91-3242 (1991)] and the underlined nucleotides of the primer encode a *Bam*HI site.

- 28 -

The forward primer used to generate PCR fragments encoding the light chain variable region was primer LFR1-3, the sequence of which is set out below in IUPAC nomenclature as SEQ ID NO: 3.

Forward Primer LFR1-3 (SEQ ID NO: 3)

5

CGATACGAATTCGATRTTKTGATGACYCARRCTSCA

The 3' end of primer LFR1-3 corresponds to the mature amino-terminal region of the mouse immunoglobulin light chain (residues 1-8) and the underlined nucleotides encode an *Eco*RI site to facilitate cloning. The reverse primer for the light chain variable region was primer LKC-1, the sequence of which is set out below as SEQ

10

ID NO: 4.

Reverse Primer LKC-1 (SEQ ID NO: 4)

GCTATCGGATCCACTGGATGGTGGGAAGATGGA

15

The 3' end of primer LKC-1 is complementary to codons 116-122 in the constant region of the mouse kappa light chain gene (according to the numbering system of Kabat *et al.*, *supra*). The underlined nucleotides in the primer encode a *Bam*HI site.

20

The resulting light and heavy chain PCR fragments were ligated into different vectors and eight to twelve independent clones were sequenced on both strands. The DNA and amino acid sequences corresponding to the heavy chain variable region of 23F2G are shown in SEQ ID NO: 5. The seven amino-terminal residues of the heavy chain sequence are indefinite because they correspond to the forward primer used in the PCR reaction. Amino acid residues 1 to 15, 31 to 45, 53 to 84 and 94 to 103 of SEQ ID NO: 5 comprise the framework regions of the mouse 23F2G heavy chain variable domain while amino acid residues 16 to 30, 46 to 52 and 35 to 93 of SEQ ID NO: 5 comprise the CDR regions. Comparison of the translated heavy chains variable sequence to the different subgroups of variable regions of mouse heavy chains [Kabat *et al.*, *supra*] indicates that the heavy chain variable sequence of 23F2G belongs in mouse subgroup II. The DNA and deduced amino acid sequences of the light chains variable region of 23F2G are shown in SEQ ID NO: 6. The eight amino-terminal residues of the light chain were elucidated through amino-terminal sequencing of the light chain protein. Amino acid residues 1 to 30,

25

30

- 29 -

36 to 49, 67 to 98 and 110 to 120 of SEQ ID NO: 6 comprise the framework regions of the mouse 23F2G light chain variable domain while amino acid residues 31 to 35, 50 to 66 and 99 to 109 of SEQ ID NO: 5 comprise the CDR regions. The light chain variable region of 23F2G is most similar to the subgroup III mouse light chain variable regions [Kabat *et al.*, *supra*].

5

#### B. Design of Humanized Heavy and Light Chain Variable Regions

In choosing human frameworks, two general criteria were used: (1) the human frameworks chosen were as homologous as possible to those of 23F2G in order to increase the probability that the CDR regions would retain their correct conformations and consequently their affinity towards the antigen [see Kabat, *et al.*, *supra*, and Kirkham *et al.*, *EMBO J.*, 11:603-609 (1992)] and (2) the human framework regions chosen contained a minimal number of unusual residues that could potentially provoke an immune response against the antibody in a human.

Because the heavy chain of mAb 23F2G resides in the mouse subgroup II sequences, it is most homologous to sequences in human subgroup I. Therefore, a framework from the human subgroup I set of heavy chain variable sequences was chosen for use in a humanized version of mAb 23F2G. Rather than choose a particular framework from existing sequenced human antibodies, it was decided to use a consensus sequence for the human subgroup I variable region framework (Kabat, *et al.*, *supra*) so that the unusual residues often found in particular frameworks were avoided. The combined framework regions of the heavy chain of 23F2G, excluding the amino-terminal seven amino acids, have 70% sequence identity to the human subgroup I consensus sequence. In comparison, the combined 23F2G heavy chain framework regions were less homologous to the human subgroup II and III consensus sequence (52% and 58%, respectively).

10

20

25

Replacement of rodent antibody framework regions with human framework sequences can result in an antibody with significantly reduced binding affinity. In such cases, it is necessary to substitute certain human framework residues with those in the original rodent antibody. Based on an analysis of published

- 30 -

antibody humanization studies including Co *et al.*, *J. Immunol.*, 148:1149-1154 (1992); Carter *et al.*, *Proc. Nat'l. Acad. Sci. (USA)*, 89:4285-4289 (1992); Maeda *et al.*, *Hum. Antibod. Hybridomas*, 2:124-134 (1991); Kettleborough *et al.*, *Protein Engineering*, 4(7):773-783 (1991); Tempest *et al.*, *BIO/TECHNOLOGY*, 9:266-271 (1991); Gorman *et al.*, *Proc. Nat'l. Acad. Sci. (USA)*, 88:4181-4185 (1991); Queen *et al.*, *Proc. Nat'l. Acad. Sci. (USA)*, 86:10029-10033 (1989); and Co *et al.*, *Proc. Nat'l. Acad. Sci. (USA)*, 88:2869-2873 (1991), it was decided to retain the framework residues of mouse 23F2G at positions 66, 67 and 93 (numbering system of Kabat *et al.*, *supra*) which correspond to amino acid positions 60, 61 and 90 of SEQ ID NO: 5, rather than use the human subgroup I residues at these positions in the humanized heavy chain.

A similar rationale was followed in humanizing the 23F2G light chain variable domain. The variable region framework sequences of the light chain of 23F2G are 71%, 69% and 72% identical to the human subgroup I, II, and III kappa consensus sequences, respectively. It was decided to use the human kappa subgroup I consensus framework sequence because it was highly homologous to that of 23F2G and because subgroup I frameworks have most commonly been used to humanize light chain variable regions. No mouse-specific residues were substituted in the light chain human framework regions.

The sequences designed for the humanized form of the 23F2G light and heavy variable regions consisted of the framework regions of the human variable region framework sequences as described above and the CDR regions of mouse mAb 23F2G. The DNA and deduced amino acid sequences of these humanized heavy and light chains variable regions are presented in SEQ ID NOs: 7 and 8, respectively. Amino acids residues 1 to 30, 36 to 49, 67 to 98 and 110 to 120 of SEQ ID NO: 7 comprise the framework regions of the humanized heavy chain variable domain, while amino acids residues 31 to 35, 50 to 66 and 99 to 109 of SEQ ID NO: 7 comprise the CDR regions. Amino acids residues 1 to 23, 39 to 53, 61 to 92 and 101 to 111 of SEQ ID NO: 8 comprise the framework regions of the humanized light chain

- 31 -

variable domain, while amino acids residues 24 to 38, 54 to 60 and 93 to 100 of SEQ ID NO: 8 comprise the CDR regions.

C. Assembly of Humanized 23F2G Variable Region Domains

Two DNA fragments which together encoded the humanized version of the heavy chain variable region of 23F2G were assembled from complementary synthetic oligonucleotides 50-60 nucleotides in length. Sequences included in addition to sequences encoding the variable domain were (1) a HindIII restriction site at the 5' end to facilitate attachment to a promoter sequence, (2) an optimal translation initiation sequence just upstream of the initiator methionine, (3) DNA encoding a signal peptide, (4) a splice donor site just 3' to the variable region, and (5) an EcoRI site at the 3' end to facilitate attachment to the constant region DNA segment. The DNA sequence encoding the signal peptide was designed to be the same as that encoding the signal peptide associated with several human heavy chain subgroup I sequences (Kabat *et al.*, *supra*). Two DNA fragments together encoding the humanized light chain variable region DNA segment were also constructed from complementary synthetic oligonucleotides. The assembled heavy and light chain variable region DNA fragments were then cloned into pSK+ (Stratagene, La Jolla, CA) and their sequence was confirmed.

D. Construction of a Humanized 23F2G Heavy Chain Expression Vector

A plasmid for expression of the humanized heavy chain of 23F2G was constructed by ligating together the two DNA fragments containing the humanized heavy chain variable region sequence, the constant regions of the human IgG<sub>4</sub> gene [cloned from a human T cell line (Hut 78)], and the expression vector pRc/CMV (Invitrogen). The expression vector pRc/CMV contains the immediate early promoter from the cytomegalovirus (CMV), a polylinker region downstream of the promoter, and a neomycin resistance cassette. Specifically, the following four fragments were isolated and ligated: (1) the 5.5 kb HindIII/XbaI fragment from pRc/CMV, (2) a 6 kb EcoRI/XbaI fragment containing the IgG<sub>4</sub> sequences, (3) a ~ 200 bp HindIII/XbaI

- 32 -

fragment containing the 5' half of the humanized heavy chain variable region sequence, and (4) a ~300 bp XhoI/EcoRI fragment containing the 3' half of the heavy chain variable region sequence.

The ligation mix was used to transform *E. coli*, and a correct clone was confirmed by restriction digest and was designated pRc/HF2GH.2. A circular map of pRc/HF2GH.2 is shown in FIGURE 5. Large scale plasmid preparations of pRc/HF2GH.2 were performed using the alkaline lysis method as described in Sambrook *et al.*, *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Press (1989) and the plasmid was twice-banded in CsCl-ethidium bromide gradients.

10      E.    Construction of a Humanized 23F2G Light Chain Expression Vector

A plasmid for expression of the humanized light chain was constructed by ligating together two DNA fragments containing the humanized light chain variable region sequence, the human kappa gene, a dihydrofolate reductase (DHFR) gene expression cassette, and a part of the pRc/CMV vector containing the strong promoter from CMV.

In constructing a plasmid containing the humanized light chain gene of 23F2G and DHFR sequences, several intermediate plasmids were first constructed. The first intermediate plasmid constructed, pRc/HF2GL.1, was similar to that made for expression of the heavy chain gene in that the variable and constant region coding sequences were cloned between the HindIII and XbaI sites of pRc/CMV. To create pRc/HF2GL.1 the following 5 fragments were ligated together: (1) HindIII/XbaI digested pRc/CMV, (2) a ~200 bp HindIII/Asp718 fragment containing the 5' half of the humanized light chain variable region sequence, (3) a ~200 bp Asp718/EcoRI fragment containing the 3' half of variable region gene, (4) a ~400 bp EcoRI/SacI fragment containing the 5' half of kappa gene fragment (cloned from a human genomic DNA library) and (5) a ~350 bp SacI/XbaI fragment containing the 3' half of kappa gene fragment (also cloned from the human genomic DNA library).

20      A second intermediate plasmid, pS11190-dhfr, was made by inserting a 1.7kb SphI/BamHI fragment from pSV2-dhfr (ATCC 37146) into the corresponding

- 33 -

site in the polylinker of the sequencing vector pSL1190 (Pharmacia, Piscataway, NJ). The SV40-DHFR sequences within pSL1190-dhfr were completely sequenced and were found to contain only minor differences from previously published sequence of these elements. In particular, the DHFR coding sequence within pSL1190-dhfr was found to encode the same polypeptide as the previously published sequence of mouse DHFR [Simonsen and Levinson, *Proc. Natl. Acad. Sci. USA*, 80:2495-2499 (1983)].

To create a final plasmid (pD/HF2GL.1) for expression of humanized 23F2G light chain, the following four fragments were ligated: (1) the 3.1 kb BamHI/HindIII fragment from pRc/CMV, (2) the 0.753 bp XbaI/Asp718 fragment from pRc/CMV, (3) the 1.2 kb fragment from pRc/HF2GL.1 (containing the complete humanized light chain gene), and (4) the 1.7 kb Asp718/BamHI fragment (containing SV40 promoter-DHFR sequences) from pSL1190-dhfr. A circular map of pD/HF2GL.1 is shown in FIGURE 6. Large scale preparations and purifications of these plasmids were performed as described above for the heavy chain expression plasmid.

#### F. Transfection of the CHO Cell Line DXB11 and Gene Amplification

Lipofection was used to introduce both the heavy and light chain expression plasmids into the dhfr CHO cell line DXB11. Similar dhfr CHO cell lines are described in Urlaub, *et al*, *Proc. Natl. Acad. Sci. USA*, 77:4216-4220 (1980). Selection for cells that were able to grow in the absence of nucleosides (selects for DHFR) and that were resistant to G418 (neomycin) ensured that transfecants contained both plasmids.

A pool of three transfectants was subjected first to 25nM and then 100nM methotrexate (Sigma, St. Louis, MO) to select cells that had undergone amplification of the DHFR gene. After limited dilution cloning, one resulting cell line, designated 6E6 (A.T.C.C. CRL 11398) was found to produce humanized 23F2G at a rate of about 1 ng/cell/day and accumulate 5-10 mg antibody per liter of growth medium. Another cell line derived by transfection of the dhfr CHO cell line [Urlaub, *et al.*, *Cell*, 33: 405-412 (1983)] was isolated in a similar manner to cell line 6E6 and

- 34 -

6E6 and was named B13-24 (A.T.C.C. CRL 11397). Cell line B13-24, which is resistant to 200nM methotrexate, produces over 100 mg/l of antibody at a rate of about 25 pg/cell/day.

The 6E6 and B13-24 cell lines can be cultured in Dulbecco's modified Earls Medium/Ham's F-12 (1:1 mix) with 5% heat inactivated fetal bovine serum at 37°C, 6% carbon dioxide and 100% humidity, and at a density of between  $2 \times 10^5$  and  $6 \times 10^5$  cells per milliliter. The media for the 6E6 cell line includes 100nM methotrexate while the media for B13-24 cell line includes 200nM methotrexate.

Humanized 23F2G antibody was purified from the 6E6 and B13-24 cell lines as follows. Cell harvest fluid was first passed through a Protein A column, which binds IgGs. The column was washed with 35mM Tris buffer, 0.1% Tween 20, pH 7.85 and then with 50mM citrate, pH 5.0. The antibody was eluted with 50mM citrate, 0.02% Tween 20, pH 3.0, and kept under acidic conditions at room temperature for 15 minutes. The eluate was then chilled to 2-8°C and neutralized with cold 1M Tris buffer. The Protein A eluate was adjusted to 0.5M ammonium sulfate, 25mM Tris, pH 8.0 and loaded onto a Phenyl Sepharose column. The column was then washed with loading buffer (0.5M ammonium sulfate, 25mM Tris, pH 8.0), and eluted with 0.1M ammonium sulfate, 25mM Tris, pH 8.0. The eluate was then diluted 1/10 with purified water to prepare it for the next step. The diluted phenyl sepharose eluant was loaded onto a DEAE Sepharose Fast Flow column that has been equilibrated with 10mM Tris, pH 7.5. After loading, the column was washed with 10mM Tris, pH 7.5, followed by 10mM Tris, 50mM NaCl, pH 7.5. The antibody was eluted with 10mM Tris, 200mM NaCl, pH 7.5. The DEAE eluate is loaded onto a Sephadex G-25 Superfine column, and washed through with the final formulation buffer (50mM sodium acetate, 120mM NaCl, 0.02% Tween 20, pH 5.6). The eluted antibody was then diluted to the required concentration.

- 35 -

G. The Heavy Chains Derived from Cell Lines 6E6 and B13-24

During the course of analysis of mRNA derived from cell line 6E6 it was noted that most (but not all) of the RNA encoding the humanized 23F2G heavy chain was longer than expected. Subsequent cloning and sequencing of several cDNAs encoding the heavy chain revealed that a region in the DNA near that encoding the C-terminus had undergone a recombination event such that the sequence encoding the Gly-Lys sequence typically found at the C-termini of IgG<sub>4</sub> heavy chains was missing and was replaced by the sequence encoding Asp-Ser-Asn-Leu-Trp-Asn (SEQ ID NO: 9).

10 The heavy chain mRNA derived from the cell line B13-24 is the expected size and therefore the C-terminal coding region of the heavy chain produced by cell line B13-24 is likely to be intact.

H. Affinity of the Humanized 23F2G Antibodies

15 Humanized 23F2G antibody competes effectively with fluorescent murine 23F2G antibody in a cell binding assay. Fluorescent murine 23F2G antibody at 0.4 µg/ml was mixed with increasing amount of humanized 23F2G antibody. These antibody mixtures were incubated with the LFA-1 positive cell line HUT-78. After washing the cells were examined by flow cytometry for mean fluorescent intensity. In this assay humanized 23F2G antibody (at 1.01 µg/ml) bound to LFA-1 20 positive cells as efficiently as murine 23F2G antibody.

**EXAMPLE 7**

In order to further characterize the effects of murine monoclonal antibody 23F2G (referred to in this example as "M23F2G") and the humanized antibody obtained from CHO 6E6 cells of Example 6 ("Hu23F2G"), additional 25 *Macaca Fascicularis*

monkeys were sensitized to myelin BP in the manner of Example 1 using 0.1 ml of a freshly prepared, somewhat more potent emulsion comprising 0.1-0.4 mg of monkey BP and 0.5 mg of heat-killed *M. tuberculosis*. M23F2G was purified from

- 36 -

ascites fluid as in Example 5 and contained 5.2 endotoxin units per mg. Hu23F2G was purified from CHO cell 6E6 (A.T.C.C. CRL 11398) culture supernatant by affinity chromatography on Protein A under pyrogen-free conditions and contained 1.2 endotoxin units per mg.

5 Treatment was started on the day of onset of disease. Treatment groups consisted of dexamethasone (4 mg/kg/day for 3 days) alone, dexamethasone plus M23F2G (2 mg/kg/day for 7 days), or dexamethasone plus Hu23F2G (2 mg/kg/day for 7 days). Treatment assignment of animals was made prior to the onset of clinical disease. Seven animals were treated with dexamethasone, five with  
10 M23F2G, and four with Hu23F2G.

The endpoints used to evaluate the effects of treatment were: overall survival after onset of disease up to a maximum of 42 days; clinical score following treatment; and lesion burden (determined by MRI) following treatment. Clinical signs were monitored daily until time of death or sacrifice. Animals were scanned by MRI  
15 once a week. A modified clinical scoring system (vis-a-vis the previous scoring system in Table 1) was used to reflect the severity of disease and is set out in Table 6, below. Pre-treatment MRI scan data was obtained at onset ( $\pm$  3 days) of clinical disease; post-treatment scan data was obtained on 10 days after clinical onset ( $\pm$  3 days). MRI scans were analyzed by the software package NIH Image Version 1.44  
20 (Bethesda, MD) to quantitate areas of abnormality. These MRI lesions reflect brain edema and cellular infiltration caused by EAE and allow a non-invasive method of assessing the effect of treatment on brain inflammation.

- 37 -

**TABLE 6**  
**CLINICAL SIGNS AND GRADES OF EAE IN MACAQUES**

Score	Clinical Sign
1	Anorexia, weight loss
5	Inactivity, slow response, facial rash, hyperactivity, yawning
3	Apathy, drooling
4	Nystagmus, transient tremor
5	Hypokinesis, clumsiness
6	Ataxia, pupillary signs, ptosis strabismus, blindness
10	Head tilt, tremor
8	Seizure, body twisting, paresis
9	Paraplegia, hemiplegia, quadriplegia, lethargy, semicoma
10	Death

15 Survival data are shown in Table 7 below. The mean survival for the dexamethasone group was 23.4 days, compared with 34.8 days in the M23F2G group and 25.5 days in the Hu23F2G group. No statistical significance could be assigned to the survival scores for the antibody treated animals compared to those of the dexamethasone treated animals, likely due to the potency of the BP preparation.

- 38 -

TABLE 7  
SURVIVAL AFTER TREATMENT (DAYS)

	(Animal No.) <u>Dexamethasone</u>		(Animal No.) <u>M23F2G</u>		(Animal No.) <u>Hu23F2G</u>	
5	T89241	24	T89341	42	91339	11
	91444	8	91424	42	F91307	42
	91449	42	91425	6	M91353	42

10	F91337	3				
	F91304	42				
	Mean	23.4		34.8		25.5
	SD	± 18.7		± 16.1		± 19.1

Clinical score and lesion area were determined at onset of disease ( $\pm$  15 3 days) and ten days post treatment ( $\pm$  3 days), except for two animals in the dexamethasone group (92152 and F91337) that died three days after onset, and the post scan was obtained on the day of death. The values for each of the 3 treatment groups are shown in Table 8. Clinical score values shown in Table 8 were those obtained on the same day as the scan. There was no significant difference between 20 clinical scores at onset of disease between the three treatment groups; however, statistically significant differences were noted post-treatment in both clinical score and lesion area. [1-p for clinical scores, onset versus post; Dex=.73, M23F2G=.004, Hu23F2G=.0001; 1-p for lesion area, onset versus post, Dex=.27, M23F2G=.007, Hu23F2G=.07].

30 In summary, M23F2G and Hu23F2G have the same beneficial effect on monkey EAE as antibody 60.3 in terms of survival. Analyses of clinical severity and MRI endpoints also supports a beneficial effect of M23F2G and Hu23F2G compared to dexamethasone alone in monkey EAE.

- 40 -

The foregoing examples describe a method for treatment for inhibiting inflammatory processes and alleviating symptoms associated with inflammatory disease states by administering a reagent, such as an antibody, that blocks leukocyte adhesion and migration to inflammatory sites. While the present invention has been described in terms of specific methods and compositions, it is understood that variations and modifications will occur to those skilled in the art upon consideration of the description of the present invention. As one example, while two anti-CD18 mAbs, 60.3 and 23F2G, have been demonstrated to be useful in practice of methods of the invention, it is expected that any antibody which competes with mAb 60.3 and/or with 23F2G for binding to LFA-1 will also be useful, whether or not such antibody recognizes an epitope present on CD18. Accordingly, it is intended in the appended claims to cover all such equivalent variations which come within the scope of the invention as claimed.

## INDICATIONS RELATING TO A DEPOSITED MICROORGANISM

(PCT Rule 13bis)

<b>A. The indications made below relate to the microorganism referred to in the description on page _____, line _____.</b>		<b>See attached sheet</b>
<b>B. IDENTIFICATION OF DEPOSIT</b>		
Further deposits are identified on an additional sheet <input checked="" type="checkbox"/>		
Name of depositary institution  American Type Culture Collection		
Address of depositary institution (including postal code and country) 12301 Parklawn Drive Rockville, Maryland 20852 United States of America		
Date of deposit See attached sheet	Accession Number See attached sheet	
<b>C. ADDITIONAL INDICATIONS</b> (leave blank if not applicable) This information is continued on an additional sheet <input type="checkbox"/>		
"In respect of those designations in which a European patent is sought, a sample of the deposited microorganism will be made available until the publication of the mention of the grant of the European patent or until the date on which the application has been refused or withdrawn or is deemed to be withdrawn, only by the issue of such a sample to an expert nominated by the person requesting the sample (Rule 23(4) EPC)."		
<b>D. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE</b> (if the indications are not for all designated States)		
<b>E. SEPARATE FURNISHING OF INDICATIONS</b> (leave blank if not applicable)		
The indications listed below will be submitted to the International Bureau later (specify the general nature of the indications e.g., "Accession Number of Deposit")

<u>Cell Line</u>	<u>Application Page</u>	<u>A.T.C.C. Accession No.</u>	<u>Deposit Date</u>
23F2G	25	HB 11081	June 30, 1992
6E6	34	CRL 11398	July 9, 1993
B13-24	34	CRL 11397	July 9, 1993

**WHAT IS CLAIMED IS:**

1. A method for inhibition of inflammatory processes and alleviation of symptoms associated with the multiple sclerosis disease state comprising administering a therapeutically effective amount of an anti-CD18 integrin antibody substance.
2. The method of claim 1 wherein said anti-CD18 antibody is mAb 60.3.
3. The method of claim 1 wherein said anti-CD18 antibody is mAb 23F2G produced by hybridoma cell line 23F2G, A.T.C.C. HB 11081.
4. The method of claim 1 wherein said anti-CD18 antibody is a recombinant human antibody comprising a murine complementarily determining region of mAb 23F2G produced by hybridoma cell line 23F2G, A.T.C.C. HB 11081.
5. Hybridoma cell line 23F2G, A.T.C.C. HB11081.
6. CHO cell line 6E6, A.T.C.C. CRL11398.
7. CHO cell line B13-24, A.T.C.C. CRL11397.
8. Monoclonal antibody 23F2G produced by hybridoma cell line 23F2G, A.T.C.C. HB 11081.
9. Monoclonal antibody 6E6 produced by CHO cell line 6E6, A.T.C.C. CRL11398.
10. Monoclonal antibody B13-24 produced by CHO cell line B13-24, A.T.C.C. CRL11397.
11. A method for inhibition of inflammatory processes and alleviation of symptoms associated with the multiple sclerosis disease state comprising administering a therapeutically effective amount of monoclonal antibody which competes with mAb 60.3 for binding to LFA-1.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US93/06734

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) : A61K 39/395; C07K 15/28; C12N 5/12  
US CL : 424/85.8; 435/240.27; 530/388.73

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 424/85.8; 435/240.27, 70.21; 530/388.73

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

CAS, Medline, Biosis, APS

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category <sup>a</sup>	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
P,X	US, A, 5,147,637 (Wright et al.) 15 September 1992, claims.	1-5, 8 and 11
Y	Science, Volume 252, issued 21 June 1991, Waldmann, "Monoclonal antibodies in diagnosis and therapy", pages 1657-1662, See entire document.	1-11
Y	Lancet, Volume 336, Number 8727, issued 01 December 1990, "Adhesion molecules in diagnosis and treatment of inflammatory diseases", see entire abstract.	1-11

Further documents are listed in the continuation of Box C.

See patent family annex.

"A"	Special category of cited documents	T	later documents published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"B"	earlier documents published on or after the international filing date	X*	documents of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"C"	documents which may show features of priority claimed or which is cited to establish the publication date of another citation or other special reason (as specified)	Y*	documents of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"D"	documents relating to an oral disclosure, use, exhibition or other event	Z*	document number of the patent family
"E"	documents published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search

29 September 1993

Date of mailing of the international search report

OCT 14 1993

Name and mailing address of the ISA/US  
Commissioner of Patents and Trademarks  
Box PCT  
Washington, D.C. 20231
